Mastering Offline Attribution

Connecting Digital Ads to In-Store Sales Boosts ROAS & Drops Store Visit Costs by Over 30%

A multi-location furniture retailer with a large physical store footprint faced a common challenge: fragmented data and a lack of granular customer insights.

With a wide range of product categories and a diverse customer base, the client struggled to understand how their digital marketing efforts across channels directly influenced high-ticket, in-store purchases.

Adtaxi transformed their strategy by implementing a multi-layered, data-driven framework that connected offline CRM and POS data with online ad signals. Moving beyond basic web metrics like clicks and impressions, Adtaxi built an automated data pipeline using secure weekly cloud uploads to route sales data into ad platforms via conversion APIs.

This setup enabled deterministic offline attribution, allowing Adtaxi to map digital ad exposures directly to physical store visits and in-store transactions. By categorizing buyers by product interest and purchase history, Adtaxi created high-intent lookalike audiences, implemented strategic buyer suppression, and executed tailored messaging across social, programmatic display, paid search, and CTV. Advanced local household-level TV attribution further closed the loop between digital reach and local foot traffic.

The results demonstrated the power of closed-loop measurement. Adtaxi dramatically improved campaign efficiency, cutting the average cost per physical store visit by over 30% while boosting overall ROAS by nearly 30%. Lookalike audience strategies delivered even stronger efficiency gains, reducing store visit costs by more than half. By providing clear visibility into offline revenue, Adtaxi gave the retailer the data foundation needed to drive profitable, scalable growth across all locations.

CHALLENGES

Siloed online and in-store customer data

Inability to measure offline store revenue

Inefficient, last-click marketing models

SOLUTIONS

Automated offline POS and CRM data pipeline

Omnichannel targeting with Meta and TTD APIs

Closed-loop attribution for store visits

RESULTS

32.1%
Decrease in Average Cost Per Store Visit

27.9%
Increase in Average Total ROAS

56.9%
Decrease in Average Cost Per Store Visit for Lookalike Audiences

Driving Measurable Business Outcomes

Furniture retailers operating physical storefronts often struggle with a fundamental marketing disconnect: measuring how digital advertising drives physical store revenue. This client managed multiple product categories across a vast customer base, yet their data lived in silos. Online marketing signals were entirely detached from offline POS transactions and CRM records. Relying on standard digital metrics like clicks and online conversions provided an incomplete view of performance. Because high-ticket retail purchases typically involve online research followed by an in-store transaction, last-click attribution models failed to capture the true business impact of top-and-middle-funnel channels like CTV and programmatic display. Without closed-loop visibility, the client could not accurately identify which ad channels, creatives, or geographic regions were generating actual store visits and sales.

Solving the Attribution Gap with First-Party Data Automation

To solve these attribution gaps, Adtaxi engineered an automated, data-first strategy that bridged the divide between online ad exposure and offline foot traffic and sales. Adtaxi established a secure weekly pipeline where the client uploaded unified CRM and POS sales files to an AWS S3 bucket. Adtaxi parsed this raw data and automatically distributed it across major media platforms using Meta's Offline Conversions API and TTD's Offline Conversions API. By matching first-party transaction records directly to digital ad exposures, Adtaxi established deterministic offline attribution, segmenting purchase data by distinct product categories to analyze buying behavior. This pipeline continuously fed rich offline data back into ad platforms to power predictive modeling and high-intent lookalike audience creation across social, programmatic, paid search, and CTV, while automatically adding recent in-store buyers to suppression lists to eliminate wasted ad spend. Within TTD, Adtaxi evaluated every conversion touchpoint to calculate an eROAS at the creative, ad group, and campaign levels, using zip-code-level visualization tools and purchasing power metrics to apply granular bid modifications by location. Furthermore, Adtaxi integrated CCR Local to bring household-level precision to CTV and linear advertising, closing the attribution loop on high-reach TV campaigns, while historical transaction data combined with third-party data appends enabled LTV mapping and persona-informed creative refinement.

Driving Growth Through Closed-Loop Attribution

The results decisively proved the power of closed-loop measurement and advanced programmatic optimization by delivering dramatic improvements over baseline performance. The average cost per physical store visit fell by over 30%, dropping from around $16.00 down to just over $11.00, making customer acquisition significantly more efficient. Total ROAS surged by nearly 30%, climbing from a baseline in the mid-20s (24+) to over 30.0, demonstrating the impact of precise budget allocation and targeting efficacy. Lookalike audience strategies delivered even greater efficiency gains: the average cost per store visit plummeted by over 55%, falling from over $18.00 down to under $8.00, while total ROAS for lookalike segments grew by over 30%, improving from $23.00 to $30.00. These measurable achievements provided the client with the clear revenue visibility needed to align with strategic goals, helping them unlock new growth opportunities and acquire additional stores for expansion in new locations.

Key Insights

Connecting offline POS and CRM data with digital ad networks proved that top-of-funnel channels like CTV drive significantly more in-store revenue than last-click attribution suggests. Product-level segmentation proved critical; tailoring lookalikes and messaging by specific category drastically lowered foot-traffic costs. Automated buyer suppression eliminated wasted spend, confirming that real-time offline feedback loops are essential for optimizing high-ticket retail media strategies.
